¹³ Summary

¹⁴ JAXtronomy is a re-implementation of the gravitational lensing software package lenstronomy¹
¹⁵ ([Birrer, 2021; Birrer & Amara, 2018](#)) using JAX², a Python library that uses an accelerated
¹⁶ linear algebra (XLA) compiler to improve the performance of computing software. Our core
¹⁷ design principle of JAXtronomy is to maintain an identical API to that of lenstronomy.

¹⁸ The main JAX features utilized in JAXtronomy are just-in-time-compilation, which can lead to
¹⁹ significant reductions in execution time, and automatic differentiation, which allows for the
²⁰ implementation of gradient-based algorithms that were previously impossible. Additionally, JAX
²¹ allows code to be run on GPUs, further boosting the performance of JAXtronomy.

²² Statement of need

²³ lenstronomy has been widely applied to numerous science cases, with more than 200 publications making use of the software, and has an increasing number of dependent packages relying on features of lenstronomy. For instance, science cases directly involving lenstronomy include galaxy evolution studies using strong lensing ([Anowar J. Shajib et al., 2021; Sheu et al., 2025; Tan et al., 2024](#)) and detailed lens modeling for measuring the Hubble constant using time-delay cosmography by the TDCOSMO collaboration ([Birrer, S. et al., 2020; Birrer, Simon & Treu, Tommaso, 2021; Collaboration et al., 2025; Gilman, D. et al., 2020; Millon, M. et al., 2020; Schmidt et al., 2025; A. J. Shajib et al., 2022; ?](#)).

²⁴ Examples of packages dependent on lenstronomy for general-purpose lensing computations and image modelling include the dolphin package ([Anowar J. Shajib et al., 2025](#)) for automated lens modeling, the galight package ([Ding et al., 2020](#)) for galaxy morphology measurements, SLSim (Khadka et al, 2025, in prep) for simulating large populations of strong lenses, pyHalo ([Gilman et al., 2019](#)) and mejiro ([Wedig et al., 2025](#)) for simulating strong lenses with dark matter substructure, and PALTAS ([Wagner-Carena et al., 2023](#)) for neural network inference tasks.

²⁵ In many of these applications, computational constraints are the key limiting factor for strong gravitational lensing science. For example, increased data quality and number of lenses to

¹<https://github.com/lenstronomy/lenstronomy>

²<https://github.com/jax-ml/jax>

analyze makes lens modeling a computational bottleneck, and expensive ray-tracing through tens of thousands of dark matter substructures limit the amount of images that can be simulated, especially for the training of neural networks and simulation-based inferences.

These ever-increasing computational costs have lead to the development of several JAX-accelerated strong-lensing packages, such as `gigalens` (Gu et al., 2022), `herculens` (Galan et al., 2022), `paltax` (Wagner-Carena et al., 2024), `GLaD` (Wang et al., 2025), and Google Research's `jaxstronomy`³. Such packages have been directly inspired by `lenstronomy` and/or support specific use cases. With `JAXtronomy`, we aim to support a wide range of features offered by `lenstronomy` while maintaining an identical API so that packages dependent on `lenstronomy` can transition seamlessly to `JAXtronomy`.

Improvements over lenstronomy in image simulation

The simulation of a lensed image comes in three main steps. The first step begins with a coordinate grid in the angles seen by the observer. These coordinates are ray-traced through the deflectors back to the source plane. This process requires the calculation of light ray deflection angles at each deflector. Second, the surface brightness of the source is calculated on the ray-traced coordinate grid. This produces a lensed image. Third, the lensed image gets convolved by the point spread function (PSF) originating from diffraction of the telescope optics and atmospheric turbulence. Due to the various choices in deflector mass profiles, light model profiles, grid size, and PSF kernel size, the overall runtime of the pipeline can vary significantly.

In the following sections, we outline the improvements in performance that `JAXtronomy` has over `lenstronomy` for each step in the pipeline. These performance benchmarks were run using an Intel(R) Xeon(R) Gold 6338 CPU @ 2.00GHz, an NVIDIA A100 GPU, and JAX version 0.7.0.

Deflection angle calculations

Each entry in the table indicates how much faster `JAXtronomy` is compared to `lenstronomy` at computing deflection angles for the corresponding deflector profile and grid size. Those profiles which are already computationally inexpensive for `lenstronomy` are excluded from this table. Some comparisons vary significantly with values of function arguments, so a range is given rather than a number.

Deflector Profile	60x60 grid (cpu)	180x180 grid (cpu)	180x180 grid (gpu)
CSE	1.6x	2.6x	2.6x
EPL	5.1x - 15x	9.2x - 17x	37x - 120x
EPL (jax) vs	1.4x	3.0x	13x
EPL_NUMBA			
EPL_MULTI-	2.1x - 7x	6.4x - 13x	42x - 108x
POLE_M1M3M4			
HERNQUIST	2.0x	3.4x	5.8x
HERNQUIST_EL-	3.8x	5.4x	40x
LIPSE_CSE			
MULTIPOLE	0.9x	1.0x	8.3x - 14x
MULTIPOLE_ELL	1.5x - 2.1x	2.0x - 2.8x	70x
NFW	1.6x	3.3x	4.5x
NFW_ELLIPSE_CSE	4.1x	6.7x	31x
TNFW	2.4x	5.8x	7.5x

³<https://github.com/google-research/google-research/tree/master/jaxstronomy>

70 Flux calculations

71 An analogous table for the different light profiles is shown below.

Light Profile	60x60 grid (cpu)	180x180 grid (cpu)	180x180 grid (gpu)
CORE_SERSIC	2.0x	6.7x	4.2x
GAUSSIAN	1.0x	2.5x	1.3x
GAUSSIAN_ELLIPSE	1.5x	3.6x	2.0x
SERSIC	1.0x	1.7x	3.9x
SERSIC_ELLIPSE	1.9x	5.7x	3.2x
SHAPELETS ($n_{\text{max}}=6$)	6.2x	3.4x	15x
SHAPELETS ($n_{\text{max}}=10$)	6.0x	4.5x	17x

72 FFT Convolution

73 We find that FFT convolution using JAX on CPU results in variable performance boosts or
74 slowdowns compared to lenstronomy (which uses scipy's FFT convolution). On a 60x60
75 grid, and kernel sizes ranging from 3 to 45, JAX on CPU ranges from being 1.1x to 2.9x faster
76 than lenstronomy, with no obvious correlation to kernel size. On a 180x180 grid, and kernel
77 sizes ranging from 9 to 135, JAXtronomy on CPU ranges from being 0.7x to 2.5x as fast as
78 lenstronomy, with no obvious correlation to kernel size.

79 However, FFT convolution using JAX on GPU is significantly faster than scipy. On a 60x60
80 grid, and kernel sizes ranging from 3 to 45, JAX on GPU ranges from being 1.5x to 3.5x
81 faster than lenstronomy, with JAX performing better at higher kernel sizes. On a 180x180
82 grid, and kernel sizes ranging from 9 to 135, JAXtronomy on GPU is about 10x to 20x as fast
83 as lenstronomy, again with JAX performing better at higher kernel sizes.

84 Improvements over lenstronomy in lens modelling

85 The process of lens modelling involves finding best-fit parameters describing a lensed system
86 from real data. In lenstronomy, this typically involves a Particle Swarm Optimizer (PSO)
87 (Kennedy & Eberhart, 1995) for optimization and Monte Carlo Markov Chains for posterior
88 sampling.

89 JAXtronomy retains all of the lens modelling algorithms from lenstronomy while benefitting
90 from the increased performance outlined above. Additionally, using JAX's autodifferentiation, we
91 have implemented the L-BFGS gradient descent algorithm from the Optax⁴ library (DeepMind
92 et al., 2020) for optimization. This is a significant improvement over lenstronomy's PSO,
93 which does not have access to gradient information.
